

Typical operationalisation in social movement network analysis

What is a node?

pre-given unit with attributes

What is a tie?

tie weighted by frequency of joint participation; quality established alongside the network

Where do categories sit?

categories as node attributes; their crossing can be counted, their production cannot be shown

What must persist over time?

units held constant; change registers only in ties

What can be claimed?

How often formations co-occur, and whether ties cross categories

This thesis

- generative
- - - extractive
- not qualified
- □ □ sources that qualify the tie: interview, ethnography, event
- new node

structured tendency identified through instances; the name serves only as an index

tie qualified by the relational function it carries; a trace of the relation, not a proxy

categories as operations that relations reproduce or refuse

the function must persist; units may change

What relations do, and whether this holds as a tendency across layers, sites and time

Row A shows how nodes and ties are typically operationalised. Many studies interpret networks in their context (Diani, 2011; Mische, 2011).
Schematic illustration, not a plot of the data.
